

Types of Parameter in LLM:

1. api parameter:

user give prompt +parameters to LLM, LLM does api call with the user query/prompt + parameters to AI model and AI model sends back the response back to LLM

ex.

API Parameters = Your Instructions to the Chef

Temperature = 0.8: "Make it spicy."

Max Tokens = 200: "Keep the portion small."

Does giving the chef 15 different highly-specific instructions make the food better? No, it just controls exactly how they plate it. Giving too many instructions might even ruin the dish!

2. model parameter:

AI model has billions/trillions/millions of individual numbers, model parameters are nothing but connecting these numbers inside the ai model (i.e neural network - human brain) so that the ai model can remember a concept and connect them which is nothing but an Ai model's memory and reasoning ability.

LLM with more no. of parameters will perform better. A model with 70 billion parameters has a bigger "brain" and more knowledge than a model with 8 billion parameters. It will reason better, understand complex prompts better, and perform better.

ex.

Model Parameters = The Chef's Brain (Skill Level)

A chef with 8 Billion parameters is a junior cook.

A chef with 70 Billion parameters is a master chef.

More parameters here = Better food.
