

Temperature:

Temperature is one of the parameters sent along with the prompt to query the AI model.
Controls the randomness/creativity of word choices

Temperature types:

high --> the randomness of the response from AI model is zero or high, sometimes it leads to accurate(correct) or high hallucination response from AI model

medium --> the randomness of the response from AI model is zero or medium, sometimes it leads to accurate(correct) or medium hallucination response from AI model

low --> the randomness of the response from AI model is low or zero, sometimes it leads to accurate(correct) or mild hallucination response from AI model.

for ex.

prompt: "What is the color of the sky?"

AI during decision making using training data

The prediction/answer/decision for "What is the color of the sky?" would be the below

Blue(50%)

Pink(10%)

Black(40%)

sum of all predictions options % will be equal to 100%

if temperature is high-->it can pick blue which has highest % or pink which has least %--> it includes probability of giving a chance to least % decision as well.

if temperature is medium -->it can pick blue which has highest % or it can pick Black which has medium % -->it includes probability of giving chance to medium % decision as well.

if temperature is low --> it picks blue which has highest % -->it includes probability of giving chance to highest % decision.
